### ABSTRACT

In this project, we have seen and studied thoroughly some works on the site related to post tensioned slabs. The various sizes of tendons available, which are the materials imparting prestress to the structure were studied thoroughly. We have also understood and performed building column line staking on site. We have visited the site and taken part in the execution work under the structural engineer in-charge. The unbonded tendons are typically prefabricated at a plant and delivered to the construction site, ready to install. The tendons are laid out in the forms in accordance with installation drawings that indicate how they are to be spaced, what their profile (height above the form) should be and where they are to be stressed. After the concrete is placed( from the RMC trucks) and has reached its required strength, usually about 75% of its final strength, then the prestressing process begins. The concrete grade that was used was M35 and hence, after 7 days when it achieved the strength of 25 N/mm<sup>2</sup>, prestressing was achieved through Prestressing powerpack using a mono strand stressing jack. The principle is that when the tendons are stretched, want to return to their original length but are prevented from doing so by the anchorages. The fact that the tendons are kept in a permanently stressed (elongated) state causes a compressive force to act on the concrete. The compression that results from the post tensioning counteracts the tensile forces created by the prestress applied. This significantly increases the load-carrying capacity of the concrete.

**Keywords:** Flat Slab, SAFE, Post-Tensioned Flat Slab.

### 1. INTRODUCTION

Due to rapid increase in demand for space, construction of multi-storied buildings is becoming a necessary part of our living. The limitation of space is forcing us to raise the height of buildings as much as possible to accommodate maximum number of people. Resisting lateral loads like wind and earthquake also comes into picture with increase in height of the building. Flat slab buildings can be broadly divided into RCC and Prestressed buildings. The flat slab or Post Tensioned Slab buildings in which slab is directly rested on columns, have been adopted in many buildings constructed recently due to the advantage of reduced floor to floor heights to meet the economical and architectural demands. But Punching shear failure observed during the transfer of unbalanced moment from slab to column is the main drawback of using flat slab.

Also its behavior during earthquake due to absence of beams is also the matter to study.

### 2. Flat Slabs

The traditional method of construction that is a common practice is to support slab by beam; and beam supported by column. This is called as a beam slab load transfer construction technique. Due to this traditional technique of construction net height of the room is reduced. Therefore to improve the aesthetical and structural aspect of multi-storey, shopping malls, offices, warehouses etc. are constructed in such a way where slabs are directly on columns. This type of slab which is directly supported on columns is termed as flat slabs.

#### 2.1 Floor System

The slabs are presented in two group's viz. one-way slabs and two-way slabs. When a rectangular slab is supported on all the four

sides and the length-to-breadth ratio is less than two, it is termed as a twoway slab. The slab spans in both the orthogonal directions. Rectangular two-way slabs are divided into the following types:

1) Flat plates: The Flat plate slabs do not have beams between the columns, drop panels or column capitals. Usually, there are spandrel beams at the edges.

2) Flat slabs: These slabs do not have beams but have drop panels or column capitals.

3) Two-way slabs with beams: If the beams are wide and shallow, they are termed as band beams. There are beams between the columns. These slabs can be cast-in-situ (cast-in-place). Else, the slabs can be precast at ground level and lifted to the final height. These types of slabs are called lift slabs. A slab in a framed building can be a two-way slab depending upon its length-to-breadth ( $L/B$ ) ratio.

## 1.1 Advantages of Post-tensioned Flat Slabs:

### 1. Reduction in cost:

Stronger structures are made at an affordable price by post-tensioning. There are many structures like parking garages as well as stadiums, as they are required to hold muchmore weight than average buildings; this slab becomes a feasible option.

### 2. Flexibility in design:

The designs made with this slab are sleek, require lesser space..

### 3. Lesser usage of materials:

Since the post tension slab is thin, the materials used with it are also lesser. This slab does not need bulky materials.

### 4. Durability:

Being a very strong substitute of the normal concrete, it lasts longer.

## 1.2 Disadvantages of Post-Tensioned Flat slabs:

### 1. Corrosion:

As there are a number of tendons and wires spread inside the post tension slab, it can result in corrosion. But, this tendency to

corrode depends on the quality of the material used.

### 2. Complexity of work:

Only skillful professional can manufacture post-tensioned slabs. The local workers may not have the necessary knowledge skills required to make this complex slab.

### 3. Poor workmanship can lead to accidents:

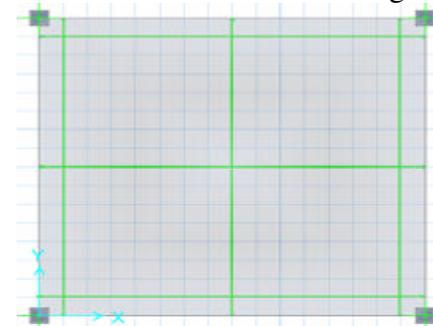

The main problem with using **post tension slab** is that if sufficient care is not taken while preparing it, it can lead to future fatal accidents.

### 1.3 Necessity:

While analyzing the post-tensioned slab, there are some secondary moment effects observed. These secondary moment effects when combined with lateral loading become a critical issue in the design of slab. Due to this, there arises an urge to study the behaviour and response of flat slabs and Post tensioned flat slabs during an earthquake. Another arising issue in the present scenario is the scarcity of space which is compelling us to raise the height of buildings to accommodate the growing population. This increase in the height of building enforces consideration of the factors such as lateral loads like wind and earthquake while design and analysis of the structure.

## 3. MODELLING AND ANALYSIS

SAFE 2D Post-tensioned flat slab model under consideration are shown in Fig.1

**Description of model:**

Floor height	3m
Depth of Slab	200mm
Grade of Concrete	M30
Grade of steel	Fe415

Flat plate considered is analyzed using SAFE and maximum bending moments and minimum bending moments are calculated in column strip and middle strip.

**Sequence No.1 :( all X cables first and then Y)**

For the above slab we tried with stretching sequence as cable no.1 at first stage then cable 2 in second stage cable no 3 in third stage cable no 4 in 4th stage cable no 5 in 5th stage cable no 6 in 6th stage. Cable 1, 2 and 3 are all X- tendons and cable 4,5and 6 are all Y- tendons.

**Sequence No.2: (alternate X and Y cables)**

For the above slab we tried with stretching sequence as cable no 1 at first stage then cable 4 in second stage, cable no 2 in third stage, cable no 5 in fourth stage, cable no 3 in fifth stage, cable no 6 in 6th stage. Where cables no 1, 2 and 3 are all X- tendons and cables no 4,5and 6 are all Y- tendons.

**4. CONCLUSIONS**

- Stretching of cables can be done 1st in xdirection then in y-direction, alternate stretching can be done to avoid the torsion of slab.
- Stretching one cable produces secondary moment and hence strip moments in both direction changes drastically.
- Hyper static moments are affecting during the construction stage. In stage wise construction hyper static moments play important role.
- In the above flat plate varying eccentricity is not very much possible due to small thickness of slab but force can be worked out for new moments.
- Due to post-tensioning of flat plates slab there is no much effect on axial force but shear and moment on column increases.
